Background

The 2021 ActEV independent evaluations will use the Multiview Extended Video with Activities ([MEVA](http://mevadata.org) <http://mevadata.org>) test video dataset for the activities as defined in the annotation guide [1]. NIST is encouraging the crowd sourcing of annotations to greatly enhance the amount of annotated MEVA training data for the activities and share them with the ActEV research community. This document describes the requirements a “sharer” must adhere to and the common data files for exchanging data. By now, you should be familiar with:

- The MEVA video data
- Reviewed the annotation exemplars
- Reviewed the annotation guidelines for both the tracked object types and the activity definitions.

To annotate a video, one must temporally localize each activity instance (in terms of the start/end the performed activity) and spatially annotate bounding boxes of object(s) associated with the activity instance.

Annotators can use any of the video annotation tools used by the video analytics community, some of the commonly used ones are described in [2][3][4][5][6][7][8][9]. Since most video annotation tools have their own output format, annotation sharers are responsible for translating their annotations into a common format, where all the data can be aggregated, compared and merged to create a training dataset.

The common annotation data format is a set of three, JSON-formatted data files that describe the video files annotated, the activities annotated within the videos, and activity instance annotations themselves.

By convention, the names of three files are:

```
file-index.json
activity-index.json
activities.json
```

Section 1 describes each of the three data file formats and the content they hold.

1. Annotation Files

Annotations are represented by three file types. (1) The **file-index** defines the list of video files annotated and metadata about the video files including the annotated frames. (2) The **activity-index** enumerates the list of annotated activities and metadata about the activities including the annotated objects. The textual description of the activities and objects are contained in the “ActEV Annotation Definitions for MEVA Data”[1]. (3) the **activities** file contains the annotations for each instance of an activity.

Each triplet of files forms a coherent set of annotations meaning a triplet could represent a single file of a single activity or multiple files for multiple activities.

These definitions will be used throughout the document:

- **“Activity Instance”**: an observed instance of activity. It could be visibly present within a single camera view or across multiple camera views (if an annotation regime supports multiview annotation which is optional).

- **“Frame State Signal”**: a signal-based representation of a given variable’s “state” at frame X which continues until the “state” changes. The data structure is a dictionary with keys being a frame number and the value being the state. The value can be either a simple data type or another dictionary.
- **“<value>”**: a dictionary key that is a name, e.g., a file name, that must be unique within the given dictionary

1.1. FILE INDEX

The file index JSON is a three-level dictionary with first being indexed by the video source file’s name and the second level representing metadata about the file. An example, along with an explanation of the fields is included below. The file JSON contains several pieces of metadata from the MEVA camera calibration data found in the MEVA data repository [10].

```
{
  "2018-03-07.16-55-00.17-00-00.admin.G329.avi": {

}

```

- <file>: A string for the name of the video file without a path and including the extension.
 - begin time: The beginning time of the recording in the form “HH-MM-SS”,
 - camera id: The camera id of the video,
 - camera model: The camera model of the file. See the MEVA Data Repo [10] for values,
 - camera resolution: The resolution of the file in the form “<width>x<height>”,
 - camera set id: The camera set the camera belongs in the form “[3|5]_<camera_id>”. See the MEVA Data Repo [10] for values.
 - camera type: The type of video recording with value “EO”, “IR”, or “EO_NIR”,
 - clip id: The clip_id of the file which is the name of file without the extension,
 - date: The collection date of the file in the form “YYYY-MM-DD”,
 - end time: The end time of the recording in the form “HH-MM-SS”,
 - filename: The path and filename for the file relative to the main data set directory,
 - facility id: The ID of the facility. Presently defined IDs are “UF1” (for “Unknown Facility”) or “KF1” (for “known Facility 1” aka the MEVA 1 data collection),
 - frame offset precision to reference clip id: The frame precision of the offset estimation from the reference camera,
 - frame offset to reference clip id: The number of frames the camera is offset from the reference camera,
 - framerate: The frame rate of the video,
 - krtd filename: The filename of the KRTD file for the video. MEVA Data Repo [10] for details. KRTD files may be available for UF1,
 - ply: A dictionary listing the location of the PLY files for the MEVA data. There are several PLY files defined on mevadata.org. The dictionary maps the name of the PLY file to the filename of the PLY file relative to the main data set directory. PLY files are not available for UF1,
 - recording site: A generalization of the camera's recording site. Values “indoor” | “outdoor”,
 - reference camera id: The camera id of the reference camera for estimating frame offsets,
 - reference clip id: The clip ID of the video file used for estimating frame offsets,
 - reference filename: Contains the dictionary key WITHIN the current JSON for the reference file. Note: if the reference file is the file itself, then the key self-referential.

- selected: a Frame State Signal with keys representing a frame number and the values being 1 (for annotated frames) and 0 (for unannotated frames) within the file <file>.
 - <framenum>: 1 or 0, indicating whether or not the activity will be annotated for the given frame. Note that records are only added here when the value changes. For example in the above sample, frames 1 through 9001 in file “2018-03-07.16-55-00.17-00-00.admin.G329.avi” are selected for annotation. The default signal value is 0 (not-selected), and the frame index begins at 1, so for file “2018-03-07.16-55-00.17-00-00.school.G422.avi”, frames 1 through 10 are not selected. Also note that the signal must be turned off at some point after it’s been turned on.
 - slot_date_time: The Slot Date Time value is a five-minute division of the recording day. The video file times are accurate to the second but rarely begin on these time boundaries so this value links together files that, for the most part, occur during the 5-minute time slice. The values are of the form “YYYY-MM-DD.HH-MM-SS”.

1.2. ACTIVITY INDEX

The activity index JSON file lists the activities annotated for ALL files enumerated in the file index. The file is a two-level dictionary with first being indexed by the activity name (as defined in the MEVA Annotation spec and the second level representing metadata about the activity. It is assumed that if an activity is present in this file, then the activity annotation files below have been annotated for that activity (even if no instance of the activity is found.) An optional field “training” can also be found, for training a system on this activity type. An example, along with an explanation of the fields is included below.

```
{
  "person_enters_vehicle": {
    "objectTypeMap": {
      "person": "*person*",
      "vehicle": "*vehicle*"
    },
    "objectTypes": [
      "vehicle",
      "person"
    ],
    "type": "known"
  },
  "person_exits_scene_through_structure": {
    "objectTypeMap": {
      "person": "*person*",
      "vehicle": "*vehicle*"
    },
    "objectTypes": [
      "vehicle",
      "person"
    ],
    "type": "known"
  },
  "person_exits_vehicle": {
    "objectTypeMap": {
      "person": "*person*",
      "vehicle": "*vehicle*"
    },
    "objectTypes": [
      "vehicle",

```

```

        "person"
      ],
      "type": "surprise",
      "training": {
        "description": {
          "filename": "activities/annotation/person_exits_vehicle.txt",
          "type": "text"
        },
        "exemplars": [
          {
            "annotation": {
              "activities":
"activities/annotation/person_exits_vehicle.activities.json",
              "file-index":
"activities/annotation/person_exits_vehicle.file-index.json"
            },
            "annotation_type": "actev",
            "domain": "extended_video",
            "filename": "activities/video/2018-03-07.16-55-00.17-00-00.school.G422.avi"
          }
        ]
      }
    }
  }
}

```

- <activity>: A string for the name of the activity as defined in the MEVA Annotation Spec.
 - objectTypeMap: Many objects are potentially annotated. This dictionary provides, for a given objectType, a regular expression for additional objects that are also considered the given objectType.
 - objectTypes: An array of strings enumerating the set of objects annotated for each instance with respect to the given activity.
 - type: either “known” and “surprise”
 - training: An optional element that is provided for surprise activities.. This dictionary provides information regarding training on an activity.
 - description:
 - filename: The path to the description.
 - type: The type of the description’s content. Presently the only value is ‘text’ for an unformatted, ASCII text file.
 - exemplars: It has to be one instance per record.
 - annotation
 - activities: The path to the activities file containing instance annotations.
 - file-index: The path to the file-index file containing video metadata.
 - annotation type: The type of annotation files for the instance. Presently, the only defined type is “actev” which is the format described in this document
 - domain: The domain of the video recording. Presently the only value is ‘extended_video’ which is a typical ActEV video.
 - filename: The path to the video containing the activity.

1.3. ACTIVITY INSTANCE ANNOTATION FILE

The activities JSON file lists the activity instances annotated for ALL files enumerated in the file index. Those file names of annotated files can be found under the “filesProcessed” key. The file is a two-level dictionary with first being indexed by the activity name (as defined in the MEVA Annotation spec) and the second level representing metadata about the activity. It is assumed that if an activity is present in this file, then the activity annotation files below have been annotated for that activity (even if no instance of the activity is found.) An example, along with an explanation of the fields is included below.

The annotation output file should be a JSON file that includes a list of videos annotated, along with a collection of activity instance records with spatio-temporal localization information (depending on the annotation). An activity detection annotation output file is included inline below, followed by a description of each field.

The annotation output is shown for videos annotated, with a collection of activity instance records with temporal localization information only. An activity detection annotation output file is included inline below, followed by a description of each field.

Note: the activity instance annotation file used for the reference (described below) is very similar to the activity instance output file produced by a system. The reference annotations do not include a processingReport and presenceConf values.

```
{
  "filesProcessed": [
    "2018-03-07.16-55-00.17-00-00.admin.G329.avi",
    "2018-03-07.16-55-00.17-00-00.school.G422.avi"
  ],
  "activities": [
    {
      "activity": "Closing",
      "activityID": 1,
      "presenceConf": 0.832,
      "localization": {
        "2018-03-07.16-55-00.17-00-00.admin.G329.avi": {
          "1": 1,
          "112": 0
        }
      },
      "objects": [
        {
          "objectType": "person",
          "objectID": 1,
          "localization": {
            "2018-03-07.16-55-00.17-00-00.admin.G329.avi": {
              "10": { "boundingBox": { "x":10, "y":30, "w":50, "h":20}},
              "20": { "boundingBox": { "x":10, "y":32, "w":50, "h":20}},
              "30": { "boundingBox": { "x":10, "y":35, "w":53, "h":20}},
              "112": {}
            }
          }
        }
      ]
    }
  ]
}
```

```
}
  ]
}
```

- filesProcessed: A required array numerating the file names processed (either by annotators or a system) and reported on by this file. Every file, even if the file was unreadable or contained no activities, must be present in the array.
- activities: An array of annotated activity instances. Each instance is a dictionary with the following fields:
 - activity: The name (e.g. “Talking”) from the MEVA Annotation Definitions [1]
 - activityID: a unique, numeric identifier for the activity instance. The value must be unique within the list of activity detections for all video source files processed (i.e. within a single activities JSON file)
 - localization: The temporal localization of the activity instance encoded as a dictionary of frame state signals indexed by the video file id(s) for which the activity instance is witnessed. Each frame state signal has keys representing a frame number and the value being 1 (the activity instance is present) and 0 (otherwise) within the given video file. Multiple Frame State Signals can be used to represent an activity instance being present in multiple video views. In this case, frame numbers are relative with respect to the video file. The frame number begins at “1” which means frame 1 corresponds to the first frame.
 - objects: An array of objects annotated with respect to the activity instance. Each unique object is represented by the following dictionary:
 - objectType: A string identifying the objects type as one of the track types defined in the MEVA Annotation Spec.
 - objectID: unique, numeric identifier for the object. The value must be unique within a single activities JSON file.
 - Localization: The temporal-spatial localization of the objectType (referred to by the record) encoded as a dictionary of frame state signals indexed by the video file id for which the object is observed. The frames for the object localization are not necessary to match the frames for the activity localization. Each frame state signal (for a given video) has keys representing a frame number and the value is a dictionary describing the spatial localization of the object. The spatial dictionary is either empty, indicating no localization (used to terminate a track or indicate an object is not visible), or has 1 key ‘boundingBox’ which is itself a dictionary described as a pixel ‘x’, ‘y’, ‘w’, and ‘h’ for the the x-position, y-position, width and height respectively. The (0,0) (x,y) position is the top left pixel. Object localization for a frame state signal is interpreted to extend from the key value frame until the next frame present in the frame state signal, or until the end of the given video if no additional frames are present.
